Project Title	Estimating the stock keeping units using Machine Learning
Maximum Marks	10 Marks

Model Optimization and Tuning Phase

The Model Optimization and Tuning Phase involves refining neural network models for peak performance. It includes optimized model code, fine-tuning hyperparameters, comparing performance metrics, and justifying the final model selection for enhanced predictive accuracy and efficiency.

Hyperparameter Tuning Documentation (8 Marks):

Model	Tuned Hyperparameters
-------	-----------------------

<p>Linear Regression</p>	<p>#importing the library for grid search from sklearn.model_selection import GridSearchCV</p> <p>The 'lr_param_grid' specifies different values for regularization strength (C), solvers (solver), and penalty types (penalty). GridSearchCV (lr_cv) is employed with 5-fold cross-validation (cv=5), evaluating model performance based on accuracy (scoring="r2 score").</p> <h2>Linear Regression Hyperparameter Tunning</h2> <pre>from sklearn.model_selection import GridSearchCV param_grid={'fit_intercept':[True,False],'copy_X':[True,False]} grid_search=GridSearchCV(lr,param_grid,cv=5) grid_search.fit(x_train,y_train)</pre> <div data-bbox="391 953 867 1146"> <p>GridSearchCV</p> <ul style="list-style-type: none"> estimator: LinearRegression <ul style="list-style-type: none"> LinearRegression </div> <pre>pred_cv=grid_search.predict(x_test)</pre>
<p>Random Forest</p>	<p>The parameter grid (make_regression) for hyperparameter tuning. It specifies different values for the number of trees (n_estimators), splitting criterion (criterion), maximum depth of trees (max_depth), and maximum number of features considered for splitting (max_features). GridSearchCV (rfc_cv) is employed with 3-fold cross-validation (cv=3), evaluating model performance based on accuracy (scoring="r2 score").</p>
<p>Decision Tree</p>	<p>The parameters (params) define a randomized search for hyperparameter tuning of the Decision Tree Regressor (DecisionTreeRegressor), including max_depth, min_samples_leaf, min_samples_split and max_features . RandomizedSearchCV is used to evaluating model performance based on r2 score(scoring="r2 score")</p>

Random Forest Hyperparameter Tunning

```
from sklearn.model_selection import GridSearchCV
from sklearn.ensemble import RandomForestRegressor
from sklearn.metrics import mean_squared_error
from sklearn.datasets import make_regression
```

```
x,y=make_regression(n_samples=1000,n_features=10,random_state=42)
```

```
n_estimators=[int(x) for x in np.linspace(start=50,stop=250,num=10)]
max_features=['auto','sqrt']
max_depth=[int(x) for x in np.linspace(0,120,num=20)]
max_depth.append(None)
min_samples_split=[2,5,10]
min_samples_leaf=[1,2,4]
bootstrap=[True,False]
```

Final Model Selection Justification (2 Marks):

Final Model	Reasoning
Random Forest	Random Forest model is chosen for its robustness in handling complex datasets and its ability to mitigate overfitting while providing high predictive r2 score.

Random Forest Regressor

```
from sklearn.ensemble import RandomForestRegressor  
from sklearn.metrics import mean_squared_error, r2_score
```

```
model=RandomForestRegressor()
```

```
model.fit(x_train,y_train)  
pred=model.predict(x_test)
```

```
print("Mean Squared Error:",mean_squared_error(y_test,pred))  
print("R2 Score:",r2_score(y_test,pred))
```

```
Mean Squared Error: 892.5601685747586  
R2 Score: 0.7279713962082139
```

Above all the models Random Forest model have the highest r2 score among all the models.

A higher r2 score is generally considered better as it indicates a more accurate and reliable model.
